

## AESB1320-15 - Solutions

12-04-17, 9:00

TN-TZ 4.25

---

The exam consists of 10 Conceptual Questions (CQs), each valid for 1 point, and 10 Exercises (EXs), each valid for 2 points. The maximum score is 30.

**Important:** Answers to conceptual questions need to be accompanied by a short (1-2 sentences) motivation of the choice. Credits for a conceptual question can only be obtained when both the answer and the motivation are correct.

Grading rules for numerical exercises:

- correct numeric value and solution: 2 points;
  - wrong numeric value, but correct solution (computational mistake): 1.5 points;
  - wrong numeric value, correct intermediate numeric value (exercise half-done): 1 point;
  - wrong solution: 0 points.
- 

### PART I: Conceptual questions

#### CQ1

The figure represents the velocity of a particle as it travels along the x-axis. At what value (or values) of  $t(s)$  is the instantaneous acceleration equal to zero?

- $t = 0$
- $t = 1$  s
- $t = 0.5$  s and  $t = 2$  s

[ b) since there the slope of the curve is zero.]

#### CQ2

Alice and Tom dive from an overhang into the lake below. Tom simply drops straight down from the edge, but Alice takes a running start and jumps with an initial horizontal velocity of 25 m/s. Neither person experiences any significant air resistance. Compare the time it takes each of them to reach the lake below.

- Alice reaches the surface of the lake first.
- Tom reaches the surface of the lake first.
- Alice and Tom will reach the surface of the lake at the same time.

[ c) since they both have the same (zero) initial velocity in the vertical direction and the only force acting after the jump is gravity, also in the vertical direction.]

### CQ3

A car is being towed at constant velocity on a horizontal road using a horizontal chain. The tension in the chain must be equal to the weight of the car in order to maintain constant velocity.

- a) True.
- b) False.

[ b ] is the car is moving with constant velocity, there is no horizontal force, hence no tension in the chain. ]

### CQ4

A brick is resting on a rough incline as shown in the figure. The friction force acting on the brick, along the incline, is

- a) greater than the weight of the brick.
- b) zero.
- c) less than the weight of the brick.
- d) equal to the weight of the brick.

[ c ] because friction only has to be equal to the component of the gravitational force along the slope, which is less than the total gravitational force (or weight). ]

### CQ5

A stock person at the local grocery store has a job consisting of the following five segments:

- (1) picking up boxes of tomatoes from the stockroom floor
- (2) accelerating to a comfortable speed
- (3) carrying the boxes to the tomato display at constant speed
- (4) decelerating to a stop
- (5) lowering the boxes slowly to the floor.

During which of the five segments of the job does the stock person do positive work on the boxes?

- a) (1) only
- b) (1) and (2)
- c) (1), (2), (4), and (5)
- d) (2) and (3)
- e) (1) and (5)

[ b ] because in (1) gravitational potential energy increases and in (2) kinetic energy increases. ]

### CQ6

Two objects are moving at equal speed along a level, frictionless surface. The second object has twice the mass of the first object. They both slide up the same frictionless incline plane. Which object rises to a greater height?

- a) Object 1 rises to the greater height because it weighs less.
- b) Object 1 rises to the greater height because it possesses a smaller amount of kinetic energy.
- c) Object 2 rises to the greater height because it contains more mass.
- d) Object 2 rises to the greater height because it possesses a larger amount of kinetic energy.
- e) The two objects rise to the same height.

[ e ] initial kinetic energy,  $\frac{1}{2}mv^2$ , is converted into gravitational potential energy,  $mgh$ , so maximum height is only dependent on initial velocity (and gravity). ]

**CQ7**

Planet Z-34 has a mass equal to  $1/3$  that of Earth and a radius equal to  $1/3$  that of Earth. With  $g$  representing, as usual, the acceleration due to gravity on the surface of Earth, the acceleration due to gravity on the surface of Z-34 is

- a)  $g/3$ .
- b)  $3g$ .
- c)  $g/9$ .
- d)  $9g$ .
- e)  $6g$ .

[ b) because  $g=GM/R^2$  and both  $M$  and  $R$  reduce by a factor of 3. ]

**CQ8**

Jacques and George meet in the middle of a lake while paddling in their canoes. They come to a complete stop and talk for a while. When they are ready to leave, Jacques pushes George's canoe with a force  $\mathbf{F}$  to separate the two canoes. What is correct to say about the final momentum and kinetic energy of the system if we can neglect any resistance due to the water?

- a) The final momentum is in the direction opposite of  $\mathbf{F}$  but the final kinetic energy is zero.
- b) The final momentum is in the direction of  $\mathbf{F}$  and the final kinetic energy is positive.
- c) The final momentum is zero and the final kinetic energy is zero.
- d) The final momentum is zero but the final kinetic energy is positive.
- e) The final momentum is in the direction of  $\mathbf{F}$  but the final kinetic energy is zero.

[ d) the force  $\mathbf{F}$  is internal to the system, so it cannot change the total momentum, which is initially zero; kinetic energy is the sum of the kinetic energy of each object, so after separating is greater than zero. ]

**CQ9**

Consider a uniform solid sphere of radius  $R$  and mass  $M$  rolling without slipping. Which form of its kinetic energy is larger, translational or rotational?

- a) Its rotational kinetic energy is larger than its translational kinetic energy.
- b) Its translational kinetic energy is larger than its rotational kinetic energy.
- c) Both forms of energy are equal.
- d) You need to know the speed of the sphere to tell.

[Moment of inertia of a solid sphere about an axis passing through its centre:  $I=2/5 MR^2$ ]

[ b)  $K_{\text{trans}}=1/2 Mv^2 > K_{\text{rot}}=1/2 I\omega^2=1/2 (2/5 MR^2) (v/R)^2= 1/5 Mv^2$ . ]

**CQ10**

A metal bar is hanging from a hook in the ceiling when it is suddenly struck by a ball that is moving horizontally (see figure). The ball is covered with glue, so it sticks to the bar. During the instant of the collision

- a) the angular momentum of the system (ball and bar) is conserved about the hook because only

- gravity is acting on the system.
- b) the angular momentum of the system (ball and bar) is conserved about the hook because neither the hook nor gravity exerts any torque on this system about the hook.
  - c) the angular momentum of the system (ball and bar) is not conserved because the hook exerts a force on the bar.
  - d) both the angular momentum of the system (ball and bar) and its kinetic energy are conserved.
  - e) both the linear momentum and the angular momentum of the system (ball and bar) are conserved.

[ b) the hook exerts no torque about itself (distance force-pivot is zero), gravity exerts no torque because the force is aligned with the line between pivot and center of gravity (angle is zero). ]

---

## PART II: Exercises 1-5

### EX1

A ball is thrown at a  $60.0^\circ$  angle above the horizontal across level ground. It is thrown from a height of 2.0 m above the ground with a speed of 25.1 m/s and experiences no appreciable air resistance.

How long does the ball remain in the air before striking the ground? [ $g=9.81 \text{ m/s}^2$ ]

[ 4.52 s ]

Only vertical motion is relevant:

$$y = y_0 + v_{0y}t + \frac{a}{2} t^2$$

where

$$y=0 \text{ m}; y_0=2 \text{ m}; v_{0y}=v_0 \sin 60^\circ=21.74 \text{ m/s}; a=g=-9.81 \text{ m/s}^2$$

Note that the other possible solution of the quadratic equation is negative, hence not acceptable.

### EX2

A rock is thrown at a window that is located 18.0 m above the ground. The rock is thrown at an angle of  $40.0^\circ$  above horizontal. The rock is thrown from a height of 2.0 m above the ground with a speed of 30.0 m/s and experiences no appreciable air resistance.

If the rock strikes the window on its upward trajectory, from what horizontal distance from the window was it released? [ $g=9.81 \text{ m/s}^2$ ]

[27.4 m]

$$v_{0x}=30 \cos 40^\circ = 23.0 \text{ m/s}$$

$$v_{0y}=30 \sin 40^\circ = 19.3 \text{ m/s}$$

In the y-direction it works as the previous exercise, with  $y=18 \text{ m}$  and  $y_0=2 \text{ m}$ , giving  $t=1.19 \text{ s}$  (the problem states "on its upward trajectory", so the smallest of the two times has to be chosen).

In the x-direction it is simply:  $x=v_{0x}t$ .

### EX3

In a ballistics test, a 1.50-g bullet is fired through a 28.0-kg block traveling horizontally to the right toward the bullet. In this test, the bullet takes 0.0114 s to pass through the block as it reverses the block's velocity from 1.75 m/s to the right to 1.20 m/s to the left with constant acceleration.

What is the magnitude of the force that the bullet exerts on the block during this ballistics test?

[7246 N]

For the block:  $v_1=v_0+at$ , with  $v_0=1.75 \text{ m/s}$  and  $v_1=-1.20 \text{ m/s} \Rightarrow a=-258.8 \text{ m/s}^2$ .

The force magnitude is:  $F=m|a|$

**EX4**

A series of weights connected by very light cords are given an upward acceleration of  $4.00 \text{ m/s}^2$  by a pull  $P$ , as shown in the figure.  $A$ ,  $B$ , and  $C$  are the tensions in the connecting cords.

What is the magnitude of the smallest of the three tensions? [ $g=9.81 \text{ m/s}^2$ ]

[276 N]

All masses have the same acceleration, so the smallest tension will be in  $A$ , since that segment is pulling the smallest total mass.

The two forces acting on the lowest weight are tension and gravity, the net force induces the given acceleration.

$F_{\text{net}}=ma=T-F_g \Rightarrow T=ma+F_g=m(a+g)$ , with  $a=4 \text{ m/s}^2$  and  $m=20 \text{ kg}$ .

**EX5**

A person pushes horizontally on a heavy box and slides it across the level floor at constant velocity. The person pushes with a  $60.0 \text{ N}$  force for the first  $9.2 \text{ m}$ , at which time he begins to tire. The force he exerts then starts to decrease linearly from  $60.0 \text{ N}$  to  $0.0 \text{ N}$  across the remaining  $9.2 \text{ m}$ .

How much total work did the person do on the box?

[828 J]

In the first segment, work is:  $W_1=dx * F_1= 9.2*60=552 \text{ J}$

In the second segment, work is (area of a triangle if you plot force versus displacement):

$W_2=dx*(F_1-F_2)/2=9.2*(60-0)/2=276 \text{ J}$

**PART III: Exercises 6-10****EX6**

In the figure, a stunt car driver negotiates the frictionless track shown in such a way that the car is barely in contact with the track at the top of the loop. The radius of the track is  $9.9 \text{ m}$  and the mass of the car is  $1800 \text{ kg}$ . The car can be treated as a point mass. [ $g=9.81 \text{ m/s}^2$ ]

What is the magnitude of the force between the car and the track when the car is at point  $A$ ?

[35.316 kN]

At the top, energy is only potential:  $E_{\text{top}}=mgh=2mgR$  (if referred to the bottom)

At point A, energy is both potential and kinetic:  $E_A=U+K=mgR+1/2 mv_A^2$

There is no friction and gravity is conservative, so energy is conserved, which allows to compute the velocity at A:

$$mgR+1/2 mv_A^2=2mgR \Rightarrow v_A^2=2gR$$

Knowing the velocity, one can compute the centripetal acceleration in A:

$$a_c=v_A^2/R=2g$$

At A, the only force between car and track is the centripetal force (gravity is perpendicular):

$$F=ma_c=2mg$$

### EX7

A plate falls vertically to the floor and breaks up into three pieces, which slide along the floor. Immediately after the impact, a 360-g piece moves along the x-axis with a speed of 2.00 m/s and a 435-g piece moves along the y-axis with a speed of 1.50 m/s. The third piece has a mass of 100 g.

In what direction does the third piece move? Neglect any horizontal forces during the crash.

[222.2° from the x-axis]

There is no initial momentum in the horizontal plane, and horizontal forces during the crash can be neglected. Hence, in the horizontal plane, momentum is conserved and remains zero.

$$\text{X-direction: } m_1v_1+m_3v_{3x}=0 \Rightarrow v_{3x}=-7.2 \text{ m/s}$$

$$\text{Y-direction: } m_2v_2+m_3v_{3y}=0 \Rightarrow v_{3y}=-6.525 \text{ m/s}$$

Measuring the angle from the negative x-axis:

$$\theta=\tan^{-1}(v_{3y}/v_{3x})=42.2^\circ$$

Measuring from the positive x-axis, 180° needs to be added. Other reference angles are accepted, as long as it's clear where the angle is measured from.

### EX8

A uniform solid sphere starts from rest and rolls without slipping down a 35° incline that is 7.0 m long.

What is the linear speed of the center of the sphere when it reaches the bottom of the incline?

[Moment of inertia of a solid sphere about an axis passing through its centre:  $I=2/5 MR^2$ ;  $g=9.81 \text{ m/s}^2$ ]

[7.5 m/s]

$$\text{The height of the incline is: } h=7*\sin 35^\circ=4.02 \text{ m}$$

$$\text{The initial energy is only potential: } E_0=Mgh=1.5*9.81*4.02=59.15 \text{ J}$$

Final energy is only kinetic, both translational and rotational:

$$E_1=K=1/2 Mv^2 + 1/2 I\omega^2=1/2 Mv^2 + 1/2 *(2/5 MR^2)*(v/R)^2=7/10 Mv^2$$

Since energy is conserved:

$$7/10 Mv^2 = Mgh \Rightarrow v=\sqrt{10/7 gh}$$

### EX9

A turntable has a radius of 0.80 m and a moment of inertia of 2.0 kg·m<sup>2</sup>. The turntable is rotating with an angular velocity of 1.5 rad/s about a vertical axis through its center on frictionless bearings. A very small 0.40-kg ball is projected horizontally toward the turntable axis with a velocity of 3.0 m/s. The ball is caught by a very small and very light cup-shaped mechanism on the rim of the turntable (see

figure).

What percent of the initial kinetic energy of the system is lost during the capture of the ball?

[50.6%]

Before impact:  $K_0 = \frac{1}{2} I \omega_0^2 + \frac{1}{2} m v^2 = 4.05 \text{ J}$

Angular momentum is conserved:  $L_0 = I \omega_0 = L_1 = (I + m R^2) \omega_1 \Rightarrow \omega_1 = 1.33 \text{ rad/s}$

After impact:  $K_1 = \frac{1}{2} (I + m R^2) \omega_1^2 = 2.0 \text{ J}$

Percentage of kinetic energy lost:  $\%K_{\text{lost}} = (K_0 - K_1) / K_0$

### EX10

An 82.0 kg diver stands at the edge of a light 5.00-m diving board, which is supported by two narrow pillars 1.60 m apart, as shown in the figure.

- I. What is the magnitude of the force exerted on the diving board by pillar A?
- II. What is the magnitude of the force exerted on the diving board by pillar B?

[I: 1709 N; II: 2513 N]

Balance of torques about the contact point between pillar B and board:

$$\tau_A + \tau_D = 0 \Rightarrow -mg(5 - 1.6) + F_A \cdot 1.6 = 0 \Rightarrow F_A = 1709 \text{ N}$$

Balance of forces in the vertical direction:  $F_B = F_A + F_g = 1709 + 82 \cdot 9.81 = 2513 \text{ N}$
